## Constraint logic programming

 Problem: designing programming systems to reason with and about constraints.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

- CLP is a class of programming languages based on:
  - Constraint solving
  - The logic programming paradigm

## Constraint programming

Sketchpad (1963)

Interactive drawing system using static constraints

## Logic programming paradigm

An example program in pure Prolog:

```
mother_child(trude, sally).
father_child(tom, sally).
father_child(tom, erica).
father_child(mike, tom).
sibling(X, Y) :- parent_child(Z, X), parent_child(Z, Y).
parent_child(X, Y) :- father_child(X, Y).
parent_child(X, Y) :- mother_child(X, Y).
```

We can perform the query:

```
?- sibling(sally, erica).
Yes
```

## $\mathsf{CLP}(\mathcal{X})$ framework

The CLP(X) framework [JL87] is a scheme where X can be instantiated with a suitable domain of discourse, such as R, the algebraic structure consisting of uninterpreted functors over real numbers [JMSY92].

## Structure of $CLP(\mathcal{R})$ programs

- Arithmetic terms:
  - Real constants and variables are arithmetic terms
  - If  $t_1$  and  $t_2$  are terms, then  $(t_1 + t_2), (t_1 t_2), (t_1 * t_2)$  are also arithmetic terms
- Terms:
  - Uninterpreted constants, arithmetic terms and variables are terms
  - ► If f is an n-ary uninterpreted functor and t<sub>1</sub>,..., t<sub>n</sub> are terms, then f(t<sub>1</sub>,..., t<sub>n</sub>) is a term
- Constraints:
  - If  $t_1$  and  $t_2$  are arithmetic terms, then  $t_1 = t_2, t_1 < t_2$  and  $t_1 \le t_2$  are constraints
  - ► If not both t<sub>1</sub> and t<sub>2</sub> are arithmetic terms, then only t<sub>1</sub> = t<sub>2</sub> is a constraint

Structure of  $CLP(\mathcal{R})$  programs (2)

An atom is of the form

$$p(t_1, t_2, \ldots, t_n)$$

where p is a predicate symbol and  $t_1, \ldots, t_n$  are terms.

A rule is of the form

$$A_0: - \alpha_1, \alpha_2, \ldots, \alpha_k.$$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

where each  $\alpha_i$ ,  $1 \le i \le k$  is either a constraint or an atom.

► A CLP(*R*) program is a finite collection of rules.

The following program defines the relation sumto(n, s) where

$$s = \sum_{1 \le i \le n} i$$

for natural numbers n.

sumto(0,0).
sumto(N,S) :- N >= 1, N <= S, sumto(N-1,S-N).</pre>

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

## CLP by example (2)

sumto(0,0).
sumto(N,S) :- N >= 1, N <= S, sumto(N-1,S-N).</pre>

 ▶ The query S <= 3, sumto(N, S) gives rise to three answers: (N = 0, S = 0), (N = 1, S = 1), (N = 2, S = 3).
 ▶ Computation sequence for (N = 2, S = 3):

 $S \leq 3$ , sum to (N, S).

$$S \leq 3, N = N_1, S = S_1, N_1 \geq 1, N_1 \leq S_1,$$
  
sumto $(N_1 - 1, S_1 - N_1).$ 

$$\begin{split} S &\leq 3, N = N_1, S = S_1, N_1 \geq 1, N_1 \leq S_1, \\ N_1 &- 1 = N_2, S_1 - N_1 = S_2, N_2 \geq 1, N_2 \leq S_2 \\ sumto(N_2 - 1, S_2 - N_2). \end{split}$$

$$\begin{split} & S \leq 3, N = N_1, S = S_1, N_1 \geq 1, N_1 \leq S_1, \\ & N_1 - 1 = N_2, S_1 - N_1 = S_2, N_2 \geq 1, N_2 \leq S_2 \\ & N_2 - 1 = 0, S_2 - N_2 = 0. \end{split}$$

## Comparison to logic programming

- Can the power of CLP be obtained by making simple changes to LP systems [JM94]?
- In other words, can predicates in LP be regarded as meaningful constraints?

add(0, N, N). add(S(N), M, S(K)) :- add(N, M, K)

- The query add(N, M, K), add(N, M, S(K)) runs forever in a conventional LP system:
  - A global test for the satisfiability of the two add constraints is not done by the LP machinery.

- Modern DPLL-based SAT solvers feature:
  - unit propagation
  - heuristics for selecting decision variables
  - 2-literal watching
  - clause learning
  - backjumping

## Solvers for quantifier-free theories

Given a quantifier-free theory  $\mathcal{T}$ , a  $\mathcal{T}$ -solver decides the satisfiability of finite sets of atoms of  $\mathcal{T}$ .

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Decision procedures for quantifier-free theories

- Decide a boolean combination Φ of atoms of T by combining a SAT solver with a T-solver.
- Transform Φ into Φ<sub>0</sub> by replacing atoms φ<sub>1</sub>...φ<sub>t</sub> with propositional variables p<sub>1</sub>...p<sub>t</sub>
- A valuation b for Φ<sub>0</sub> is a mapping from propositional variables to {0,1}
- Define set of atoms  $\Gamma_b$  such that:

• 
$$\gamma_i = \phi_i$$
 if  $b(p_i) = 1$ 

- $\gamma_i = \neg \phi_i$  if  $b(p_i) = 0$
- $\Phi$  is satisfiable if there exists *b* that satisfies  $\Phi_0$  and such that  $\Gamma_b$  is consistent in  $\mathcal{T}$ .

# $\mathsf{DPLL}(\mathcal{T})$

- ▶ DPLL(T) is a framework which leverages the DPLL procedure and a T-solver.
- Solver must support:
  - updating the state by asserting new atoms
  - checking consistency of current state
  - backtracking
  - producing explanations for conflicts (an inconsistent subset of atoms asserted in current state)
- Solver can optionally implement theory propagation, but:
  - it must produce an explanation  $\Gamma$  for an implied atom  $\gamma$ , where  $\Gamma$  is a subset of atoms asserted in current state such that  $\Gamma \models \gamma$ .

Consider the following simple example formula  $\Phi$  in quantifier-free linear arithmetic:

$$(x+y \geq 1 \lor x+y \leq -5) \land (x=-1) \land (y=-2)$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

## Conventions

In the following, we assume that:

- The solver is initialized for a fixed formula  $\Phi$
- $\mathcal{A}$  denotes the set of atoms occurring in  $\Phi$
- $\blacktriangleright \alpha$  denotes the set of atoms asserted so far.

・ロト ・西ト ・ヨト ・ヨー うへぐ

## Interface for $\mathcal{T}$ -solver

We assume that the following API is implemented by the solver:

- Assert( $\gamma$ ): assert atom  $\gamma$  in current state.
  - if it returns ok,  $\gamma$  is inserted into  $\alpha$
  - if it returns unsat(Γ), α ∪ {γ} is inconsistent and Γ ⊆ α is an explanation.
- Check(): check whether  $\alpha$  is consistent
  - if it returns ok,  $\alpha$  is consistent, and a new checkpoint is created.
  - if it returns unsat(Γ), α is inconsistent and Γ ⊆ α is an explanation
- Backtrack(): backtrack to the last checkpoint
- Propagate(): perform theory propagation
  - ▶ it returns a set  $\{\langle \Gamma_1, \gamma_1 \rangle, \dots, \langle \Gamma_t, \gamma_t \rangle\}$  where  $\Gamma_i \subseteq \alpha$  and  $\gamma_i \in \mathcal{A} \setminus \alpha$ , such that  $\Gamma_i \models \gamma_i$  for  $1 \le i \le t$ .

## Remarks on the interface for $\mathcal{T}$ -solver

• Assert( $\gamma$ ) must be sound but need not be complete: it can return *ok* even if  $\alpha \cup \{\gamma\}$  is inconsistent.

- Check() must be sound and complete.
- $\implies$  Several atoms can be asserted in a single "batch"

## Quantifier-free linear arithmetic

A quantifier-free linear arithmetic formula is a first-order formula with atoms:

- either propositional variables
- or of the form

$$a_1x_1+\ldots+a_nx_n\bowtie b$$

where  $a_1, \ldots, a_n$  and b are rational numbers,  $x_1, \ldots, x_n$  are real (or integer variables), and  $\bowtie \in \{=, \leq, <, >, \geq, \neq\}$ .

## Linear-arithmetic solvers for $DPLL(\mathcal{T})$

Common approach: solvers based on incremental versions of the Simplex method

- Implemented in Yices, Simplics, MathSat
- Solver state includes a Simplex tableau derived from assertions
- The tableau can be seen as a set of equalities

$$x_i = b_i + \sum_{x_j \in \mathcal{B}} a_{ij} x_j, \quad x_i \in \mathcal{N}$$

where  ${\cal B}$  and  ${\cal N}$  are disjoints sets of basic and non-basic variables.

 Additional constraints are imposed, such as non-negativity of slack variables Incremental Simplex method: pivoting

Pivot(x<sub>r</sub>, x<sub>s</sub>): swap basic variable x<sub>r</sub> and non-basic variable x<sub>s</sub> such that a<sub>rs</sub> ≠ 0, by replacing

$$x_r = b_r + \sum_{x_j \in \mathcal{N}} a_{rj} x_j$$

with

$$x_{s} = -\frac{b_{r}}{a_{rs}} + \frac{x_{r}}{a_{rs}} - \sum_{x_{j} \in \mathcal{N} \setminus \{x_{s}\}} \frac{a_{rj}x_{j}}{a_{rs}}$$

and eliminating  $x_s$  from the rest of tableau by substitution.

## Incremental Simplex method operations

- To assert an atom  $\gamma$  of the form  $t \ge 0$ :
  - Normalize γ by substituting in t basic variables by non-basic ones.
  - ► Check whether resulting atom t' ≥ 0 is satisfiable by maximizing t' using the tableau.
- Asserting equalities and strict inequalities follow same principle

- To backtrack:
  - Remove rows from the tableau

## Performance issues in incremental Simplex solvers

Asserting and backtracking have significant cost, due to:

- pivoting in assertions
- frequent addition and removal of rows
- frequent creation and deletion of slack variables

## Important remarks for performance

- Generating minimal explanations is critical
- Theory propagation must be done cheaply: Full propagation is too expensive, heuristic propagation is superior

Zero detection is expensive

 $\implies$  Convert  $t \neq 0$  into  $(t > 0) \lor (t < 0)$ 

## A different solver for linear arithmetic

We now proceed to describe a solver for linear arithmetic [DdM06] with the following properties:

- It is still based on the Simplex method
- It reduces the overhead of the incremental Simplex approach

## Preprocessing

Idea: avoid incremental Simplex methods by rewriting formula  $\Phi$  into an equisatisfiable formula  $\Phi_A \wedge \Phi'$ , where:

- $\Phi_A$  is a conjunction of linear equalities
- All atoms of  $\Phi'$  are *elementary*, i.e. of the form

#### $y \bowtie b$

where y is a variable, b is a rational constant, and  $\bowtie \in \{=, \leq, <, >, \geq\}.$ 

### Example transformation

Let  $\Phi$  be the following formula:

$$x \ge 0 \land$$
$$(x + y \le 2 \lor x + 2y - z \ge 6)$$
$$\land (x + y = 2 \lor x + 2y - z > 4)$$

Introducing variables  $s_1$  and  $s_2$ , it is rewritten to  $\Phi_A \wedge \Phi'$  as:

$$egin{aligned} (s_1 = x + y \wedge s_2 = x + 2y - z) \land \ (x \ge 0 \land (s_1 \le 2 \lor s_2 \ge 6) \land (s_1 = 2 \lor s_2 > 4)) \end{aligned}$$

Properties of the rewritten formula

Formula  $\Phi_A$  can be written in matrix form as:

$$Ax = 0$$

where A is an  $m \times n$  matrix with linearly independent rows, and  $x \in \mathbb{R}^n$ .

The matrix A is fixed at all times and represents the equations

$$s_i = \sum_{x_j \in V} c_j x_j$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

where V is the set of variables of the original formula  $\Phi$ .

Properties of the rewritten formula (2)

Checking satisfiability of Φ amounts to finding x such that Ax = 0 and x satisfies Φ'.

 $\implies$  It suffices to decide the satisfiability of a set of elementary atoms  $\Gamma$  in linear arithmetic *modulo* the constraints Ax = 0.

If the elementary atoms are only equalities and non-strict inequalities, the problem consists of finding x ∈ ℝ<sup>n</sup> such that

$$Ax = 0$$
 and  $I_j \leq x_j \leq u_j$  for  $j = 1, \ldots, n$ 

where  $l_j$  is either  $-\infty$  or a rational number, and  $u_j$  is either  $+\infty$  or a rational number.

## A basic solver

- We first consider a solver that handles only equalities and non-strict inequalities with real variables.
- The solver state includes:
  - A tableau derived from A, which we can represent as:

$$x_i = \sum_{x_j \in \mathcal{N}} a_{ij} x_j \quad x_i \in \mathcal{B}$$

- Lower and upper bounds *l<sub>i</sub>* and *u<sub>i</sub>* for each *x<sub>i</sub>*
- A mapping  $\beta$  assigning a rational value to each  $x_i$
- ► Initially,  $I_j = -\infty$ ,  $u_j = +\infty$ ,  $\beta(x_j) = 0$  for all j.

## Invariants for the mapping $\beta$

The mapping  $\beta$  always satisfies the following invariants:

> The bounds on non-basic variables are always satisfied, i.e.

$$\forall x_j \in \mathcal{N}, l_j \leq \beta(x_j) \leq u_j$$

• The mapping always satisfies the constraints Ax = 0

## Main algorithm

- The main procedure is based on the dual Simplex algorithm and uses Bland's pivot-selection rule, which ensures termination.
- It assumes a total order on the problem variables.
- At a given moment, we assume that the invariants on β hold, but the mapping may not satisfy the bound constraints *l<sub>i</sub>* ≤ β(*x<sub>i</sub>*) ≤ *u<sub>i</sub>* for basic variables.

 Procedure Check() looks for a new β that satisfies all constraints.

## Check() procedure

```
1: loop
 2:
        select smallest basic var. x_i s.t. \beta(x_i) < l_i or \beta(x_i) > u_i
 3:
        if there is no such x<sub>i</sub> then
 4:
            return SAT
 5:
        else if \beta(x_i) < l_i then
 6:
            select smallest non-basic var. x_i s.t.
 7:
              (a_{ii} > 0 \land \beta(x_i) < u_i) \lor (a_{ii} < 0 \land \beta(x_i) > l_i)
 8:
            if there is no such x_i then
 9:
                return UNSAT
10:
             else
11:
                 PivotAndUpdate(x_i, x_i, l_i)
12:
             end if
13:
         else if \beta(x_i) > u_i then
14:
             select smallest non-basic var. x_i s.t.
15:
               (a_{ii} < 0 \land \beta(x_i) < u_i) \lor (a_{ii} > 0 \land \beta(x_i) > l_i)
16:
             if there is no such x<sub>i</sub> then
17:
                 return UNSAT
18:
            else
19:
                 PivotAndUpdate(x_i, x_i, u_i)
20:
             end if
21:
         end if
22: end loop
```

## Termination of Check()

#### Theorem

Procedure Check() always terminates.

Proof sketch:

- ► There is a unique tableau for any set of basic variables *B*.
- There is a finite number of possible assignments β for base B<sub>t</sub> at t-th iteration.
- ► The state of the solver at iteration t is the pair (β<sub>t</sub>, B<sub>t</sub>), and there are finitely many states reachable from S<sub>0</sub>.
- If Check() does not terminate, the sequence of states must contain a cycle.
- One can show by contradiction that such a cycle cannot occur. The correctness of the procedure is a consequence of this theorem.

#### Generating explanations

If an inconsistency is detected (say, at line 8 of Check()), then:

- There is a basic variable  $x_i$  s.t.  $\beta(x_i) < l_i$
- For all non-basic variable  $x_j$ , we have:  $a_{ij} > 0 \implies \beta(x_j) \ge u_j$  and  $a_{ij} < 0 \implies \beta(x_j) \le l_j$
- If we define  $\mathcal{N}^+ = \{x_j \in \mathcal{N} \mid a_{ij} > 0\}$  and  $\mathcal{N}^- = \{x_j \in \mathcal{N} \mid a_{ij} < 0\}$ , then, by the invariant for  $\beta$ :  $\beta(x_j) = u_j$  for all  $x_j \in \mathcal{N}^+$  and  $\beta(x_j) = l_j$  for all  $x_j \in \mathcal{N}^-$
- We therefore have:

$$\beta(x_i) = \sum_{x_j \in \mathcal{N}} a_{ij}\beta(x_j) = \sum_{x_j \in \mathcal{N}^+} a_{ij}u_j + \sum_{x_j \in \mathcal{N}^-} a_{ij}l_j$$

## Generating explanations (2)

• We have:  $\beta(x_i) = \sum_{x_j \in \mathcal{N}^+} a_{ij}u_j + \sum_{x_j \in \mathcal{N}^-} a_{ij}l_j$ • As  $x_i = \sum_{x_j \in \mathcal{N}} a_{ij}x_j$  holds for all x s.t. Ax = 0:  $\beta(x_i) - x_i = \sum_{x_j \in \mathcal{N}^+} a_{ij}(u_j - x_j) + \sum_{x_j \in \mathcal{N}^-} a_{ij}(l_j - x_j)$ 

We can then derive the implications:

$$igwedge x_{j \in \mathcal{N}^{+}} x_{j} \leq u_{j} \implies \sum_{x_{j} \in \mathcal{N}^{+}} a_{ij}(u_{j} - x_{j}) \geq 0$$

and

$$igwedge \sum_{x_j \in \mathcal{N}^-} x_j \geq l_j \implies \sum_{x_j \in \mathcal{N}^-} a_{ij}(l_j - x_j) \geq 0$$

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ○ □ ○ ○ ○ ○

## Generating explanations (3)

We have:

$$igwedge x_{j \in \mathcal{N}^{+}} x_{j} \leq u_{j} \implies \sum_{x_{j} \in \mathcal{N}^{+}} a_{ij}(u_{j} - x_{j}) \geq 0$$

and

$$\bigwedge_{x_j \in \mathcal{N}^-} x_j \geq l_j \implies \sum_{x_j \in \mathcal{N}^-} a_{ij}(l_j - x_j) \geq 0$$

Finally, we derive:

$$igwedge_{x_j \in \mathcal{N}^+} x_j \leq u_j \wedge igwedge_{x_j \in \mathcal{N}^-} x_j \geq l_j \implies x_i \leq eta(x_i)$$

- As we also have  $\beta(x_i) < l_i$ , this is inconsistent with  $l_i \leq x_i$
- Therefore we have the (minimal) explanation:

$$\Gamma = \{x_j \le u_j \mid x_j \in \mathcal{N}^+\} \cup \{x_j \ge l_j \mid x_j \in \mathcal{N}^-\} \cup \{x_i \ge l_i\}$$

## Assertion procedures

```
The Assert() function relies on two functions
AssertUpper(x_i \le c_i) and AssertLower(x_i \ge c_i):
```

```
▶ AssertUpper (x_i \leq c_i):

1: if c_i \geq u_i then

2: return SAT

3: else if c_i < l_i then

4: return UNSAT

5: else

6: u_i := c_i

7: if x_i non-basic and \beta(x_i) > c_i then

8: Update (c_i)

9: end if

10: return OK

11: end if
```

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ ─臣 ─ のへで

## Backtracking

- We only need to store:
  - the value u<sub>i</sub> before it is updated by AssertUpper
  - the value l<sub>i</sub> before it is updated by AssertLower
- In particular, we don't store successive βs on a stack: the last β obtained after a successful Check() is a model for all previous checkpoints.

## Theory propagation

#### Unate propagation

- very cheap to implement
- ▶ if bound x<sub>i</sub> ≥ c<sub>i</sub> is asserted, any unassigned atom x<sub>i</sub> ≥ c' with c' < c is implied.</p>
- useful in practice
- Bound refinement
  - Given a row of tableau:

$$x_i = \sum_{x_j \in \mathcal{N}} a_{ij} x_j$$

We can refine currently asserted bounds on  $x_i$  using bounds on non-basic variables

• Initial state:  $A_0 = \{s_1 = -x + y, s_2 = x + y\}$ 

▲□▶ ▲圖▶ ▲圖▶ ▲圖▶ = ● ● ●

► Initial state:  $A_0 = \{s_1 = -x + y, s_2 = x + y\}$ 

• Assert  $x \leq 4$

- Assert  $s_1 \leq 1$

## Handling strict inequalities

#### Lemma

A set of linear arithmetic literals  $\Gamma$  containing strict inequalities  $S = \{p_0 > 0, ..., p_n > 0\}$  is satisfiable iff there exists a rational number  $\delta > 0$  such that for all  $\delta'$  such that  $0 < \delta' \le \delta$ ,  $\Gamma_{\delta} = (\Gamma \cup S_{\delta}) \setminus S$  is satisfiable, where  $S_{\delta} = \{p_1 \ge \delta, ..., p_n \ge \delta\}$ .

- ▶ We can replace strict inequalities by non-strict ones if a small enough  $\delta$  is known
- We treat  $\delta$  symbolically instead of computing an explicit value

## Handling strict inequalities (2)

- Bounds and assignments range over the set Q<sub>δ</sub> of pairs of rationals
- $(c,k) \in \mathbb{Q}_{\delta}$  is denoted by  $c + k\delta$
- Define operations:

$$\begin{array}{rcl} (c_1, k_1) + (c_2, k_2) &\equiv & (c_1 + c_2, k_1 + k_2) \\ & a \times (c, k) &\equiv & (a \times c, a \times k) \\ (c_1, k_1) \leq (c_2, k_2) &\equiv & (c_1 < c_2) \lor (c_1 = c_2 \land k_1 \leq k_2) \end{array}$$

where *a* is a rational number.

## Defining $\delta$

If  $(c_1,k_1) \leq (c_2,k_2)$  holds in  $\mathbb{Q}_\delta$ , then we can find  $\delta_0 > 0$  such that  $c_1 + k_1 \varepsilon \leq c_2 + k_2 \varepsilon$ 

is satisfied by all positive  $\varepsilon \leq \delta_0$ . Define it as:

$$\delta_0 = \frac{c_2 - c_1}{k_1 - k_2}$$
 if  $c_1 < c_2$  and  $k_1 > k_2$   
 $\delta_0 = 1$  otherwise

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

#### Defining $\delta$ for the general case

More generally, assume we have 2m elements of  $\mathbb{Q}_{\delta}$ ,  $v_i = (c_i, k_i), w_i = (d_i, h_i)$  for  $1 \le i \le m$ . If the *m* inequalities  $v_i \le w_i$  hold in  $\mathbb{Q}_{\delta}$ , then there exists  $\delta_0 > 0$  such that

$$c_1 + k_1 \varepsilon \leq d_1 + h_1 \varepsilon$$
  
 $\vdots$   
 $c_m + k_m \varepsilon \leq d_m + h_m \varepsilon$ 

are satisfied by all positive  $\varepsilon \leq \delta_0$ . We can define:

$$\delta_0 = \min\left\{\frac{d_i - c_i}{k_i - h_i} \mid c_i < d_i \text{ and } k_i > h_i\right\}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

## Problem and solution conversion

 A problem with strict inequalities can be converted into another without strict inequalities

• Convert 
$$x_i > l_i$$
 into  $x_i \ge l_i + \delta = l'_i$ 

• Convert  $x_i < u_i$  into  $x_i \le u_i - \delta = u'_i$ 

- The basic solver described previously will give an assignment β' mapping variables to elements of Q<sub>δ</sub>, if the problem is satisfiable
- ▶ If  $l'_j = (c_j, k_j), u'_j = (d_j, h_j), \beta'(x_j) = (p_j, q_j)$ , we already know that there exists  $\delta_0 > 0$  such that

$$c_j + k_j \varepsilon \leq p_j + q_j \varepsilon \leq d_j + h_j \varepsilon$$
 for  $1 \leq j \leq n$ 

holds for all positive  $\varepsilon \leq \delta_0$ .

Define satisfying assignment β(x<sub>j</sub>) = p<sub>j</sub> + q<sub>j</sub>δ<sub>0</sub> for original problem

## Integer and mixed integer problems

- The previously described algorithm is not complete if some variables must be integers.
- A branch and cut strategy is used to be complete for the integer case. It is the combination of:

- the branch and bound algorithm
- a cutting plane generation algorithm

Consider the problem

$$Ax = 0$$
  
 $I_j \le x_j \le u_j ext{ for } 1 \le j \le n$ 

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

with the additional condition that  $x_i$  is an integer variable for  $i \in I \subseteq \{1, ..., n\}$ .

## Branch and bound (2)

- Solve the *linear programming relaxation*, i.e. search for a solution in reals
- If relaxation is infeasible, the problem is infeasible too.
- If an assignment β is found that satisfies all integer constraints, we are done.
- If there exists i ∈ I such that β(x<sub>i</sub>) ∉ Z, then solve (recursively) the two subproblems:

$$S_0: \begin{cases} Ax = 0\\ l_j \le x_j \le u_j & \text{for } 1 \le j \le n \text{ and } j \ne i\\ l_i \le x_i \le \lfloor \beta(x_i) \rfloor \end{cases} \\ S_1: \begin{cases} Ax = 0\\ l_j \le x_j \le u_j & \text{for } 1 \le j \le n \text{ and } j \ne i\\ \lfloor \beta(x_i) \rfloor + 1 \le x_i \le u_i \end{cases} \end{cases}$$

The need for a cutting plane generation algorithm

- If not all integer variables have an upper and a lower bound, branch and bound may not terminate.
- Example:

$$1 \le 3x - 3y \le 2$$

This constraint is unsatisfiable if x and y are integers. A naïve branch and bound algorithm loops on this input.

- ▶ W.I.o.g. we assume that all integer variables are bounded.
- The bounds are typically too large, and cutting plane algorithms are needed to accelerate convergence.

## Cuts

Assume  $\beta$  is a solution to the LP relaxation *P* of problem *S*, but not to *S* itself. A *cut* is a linear inequality

$$a_1x_1+\ldots+a_nx_n\leq b$$

that is not satisfied by  $\beta$  but is satisfied by any element in the convex hull of *S*.

The cut can be added as a new constraint to S, yielding a problem S'

- that has the same solutions as S
- ▶ but whose LP relaxation P' is strictly more constrained than P.

## Deriving Gomory cuts

We have:

$$\begin{aligned} x_i - \beta(x_i) &= \sum_{j \in J} a_{ij}(x_j - l_j) - \sum_{j \in K} a_{ij}(u_j - x_j) \\ x_i - \lfloor \beta(x_i) \rfloor &= f_0 + \sum_{j \in J} a_{ij}(x_j - l_j) - \sum_{j \in K} a_{ij}(u_j - x_j) \end{aligned}$$

where

$$J = \{j \in I \mid x_j \in \mathcal{N}' \land \beta(x_j) = l_j\}$$
  

$$K = \{j \in I \mid x_j \in \mathcal{N}' \land \beta(x_j) = u_j\}$$
  

$$\mathcal{N}' = \mathcal{N} \cap \{x_j \mid l_j < u_j\}$$

## Deriving Gomory cuts (2)

We have:

$$x_i - \lfloor \beta(x_i) \rfloor = f_0 + \sum_{j \in J} a_{ij}(x_j - l_j) - \sum_{j \in K} a_{ij}(u_j - x_j)$$

which holds for all x that satisfies the problem S. Furthermore, for any such x,  $x_i - \lfloor \beta(x_i) \rfloor$  is an integer and the following also hold:

$$egin{array}{ll} x_j - l_j \geq 0 & ext{ for all } j \in J \ u_j - x_j \geq 0 & ext{ for all } j \in K \end{array}$$

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

## Deriving Gomory cuts (3)

We consider two cases:

► If 
$$\sum_{j \in J} a_{ij}(x_j - l_j) - \sum_{j \in K} a_{ij}(u_j - x_j) \ge 0$$
, then:  
$$f_0 + \sum_{j \in J} a_{ij}(x_j - l_j) - \sum_{j \in K} a_{ij}(u_j - x_j) \ge 1$$

as  $f_0 > 0$  and the left-hand side is an integer. Then we have:

$$\sum_{j\in J^+}a_{ij}(x_j-l_j)-\sum_{j\in K^-}a_{ij}(u_j-x_j)\geq 1-f_0$$

where  $J^+ = \{j \in J \mid a_{ij} \ge 0\}$  and  $K^- = \{j \in K \mid a_{ij} < 0\}$ . Equivalently:

$$\sum_{j\in J^+} \frac{a_{ij}}{1-f_0} (x_j - l_j) + \sum_{j\in K^-} \frac{-a_{ij}}{1-f_0} (u_j - x_j) \ge 1$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○○○

## Deriving Gomory cuts (4)

We apply the same procedure for the other case, and combining the two cases, we obtain:

$$\sum_{j \in J^{+}} \frac{a_{ij}}{1 - f_0} (x_j - l_j) + \sum_{j \in J^{-}} \frac{-a_{ij}}{f_0} (x_j - l_j) + \sum_{j \in K^{-}} \frac{a_{ij}}{f_0} (u_j - x_j) + \sum_{j \in K^{-}} \frac{-a_{ij}}{1 - f_0} (u_j - x_j) \ge 1$$

which is a *mixed-integer Gomory cut*: it is satisfied by any x that satisfies S, but it is not satisfied by the assignment  $\beta$  (as the left-hand side is equal to 0 in that case).
