FÉDÉRALE DE LAUSANNE

Today we talk about something
new

Memory Allocation in Java

{true} (Hoare triple)

```
x = new C();
```

```
y = new C();
```

```
assert{x != y}; // fresh object references-distinct
```

Why should this assertion hold?

How to give meaning to 'new' so we can prove it?

How to represent fresh objects?

```
assume(N > 0 && p > 0 && q > 0 && p != q);  
a = new Object[N];  
i = 0;  
while (i < N) {  
    a[i] = new Object();  
    i = i + 1;  
}  
assert(a[p] != a[q]);
```

A View of the World

Everything exists, and will always exist.

(It is just waiting for its time to become allocated.)

It will never die (but may become unreachable).

$\text{alloc} : \text{Obj} \rightarrow \text{Boolean}$ i.e. $\text{alloc} : \text{Set}[\text{Obj}]$

$x = \text{new } C();$

\rightarrow

$\text{havoc}(x);$

$\text{assume}(x \notin \text{alloc});$

$\text{alloc}_1 = \text{alloc} \cup \{x\};$

$x \in \text{alloc}_1$

$\text{havoc}(y);$

$\text{assume}(y \notin \text{alloc}_1);$

$\text{alloc}_2 = \text{alloc}_1 \cup \{y\};$

$y \notin \text{alloc}_1$

\wedge default constructor

$y = \text{new } C();$

$\text{assert}(x \neq y)$

before:
 alloc

after:

New Objects Point Nowhere

```
class C { int f; C next; C prev; }
```

this should work:

```
x = new C();
```

```
assert(x.f==0 && c.next==null && c.prev==null)
```

`x = new C();` →

1) use assignment
`f = f(x := 0)`

2) use assume

[
 `havoc(x)`
 `assume(x != alloc)`
 `alloc = alloc ∪ {x}`
 `assume(f(x) == 0 ∧`
 `next(x) = null ∧`
 `prev(x) = null);`
]

If you are new, you are known by few

```
class C { int f; C next; C prev; }
```

Assume C is the only class in the program

Lonely object: no other object points to it.

Newly allocated objects are lonely!

$x = \text{new } C(); \rightarrow$

$\left[\begin{array}{l} \forall \sigma, \sigma' \in \text{alloc} \rightarrow \text{next}(\sigma) \neq x \end{array} \right.$

$\forall \sigma. \quad \sigma \in \text{alloc} \rightarrow \text{next}(\sigma) \in \text{alloc} \wedge \text{prev}(\sigma) \in \text{alloc}$

Remember our Model of Java Arrays

```
class Array {  
  int length;  
  data : int[]  
}
```

```
a[i] = x
```

length : Array \rightarrow int
data : Array \rightarrow (Int \rightarrow Int)
or simply: Array x Int \rightarrow Int

\rightarrow assert (a \neq null);
assert ($0 \leq i \wedge i < \text{length}(a)$);
data = data((a,i) := x)

```
y = a[i]
```

\rightarrow assert (a \neq null);
assert ($0 \leq i \wedge i < \text{length}(a)$)
y = data((a,i))

Allocating New Array of Objects

```
class oArray {  
  int length;  
  data : Object[]  
}
```

```
x = new oArray[100] →
```

$\text{length} = \text{length} \ (x := E)$

$\text{havoc}(x);$
 $\text{assume}(x \notin \text{alloc});$
 $\text{alloc} = \text{alloc} \cup \{x\};$
 $\text{assume}(\text{length}(x) = E_{(100)}) \wedge$

$\forall i. 0 \leq i < E \rightarrow$
 $\text{data}(x, i) = \text{null} \wedge$

$\forall \sigma \in \text{alloc}. \wedge f(\sigma) \neq x$
 $f \in \text{fields}(\text{coll})$

Procedure Contracts

Suppose there are fields and variables f_1, f_2, f_3 (denoted f)

procedure $\text{foo}(x)$:

requires $P(x, f)$

modifies f_3

ensures $Q(x, \text{old}(f), f)$

$\text{foo}(E) \rightarrow$

assert($P(E, f)$);

old_f = f ;

havoc(f_3);

assume $Q(E, \text{old_f}, f)$

Modification of Objects

Suppose there are fields and variables f_1, f_2, f_3 (denoted f)

procedure $\text{foo}(x)$:

requires $P(x, f)$

modifies $x.f_3$

ensures $Q(x, f, f')$

$\text{foo}(E) \rightarrow$

assert($P(E, f)$);

old_f = f;

havoc($x.f_3$);

assume $Q(E, \text{old_f}, f)$

$$x.f_3 = y \rightsquigarrow f_3 = f_3(x := y)$$

$$\leftarrow \begin{cases} \text{old_f}_1 = f_1 \\ \text{old_f}_3 = f_3 \end{cases}$$

$$\rightarrow \text{havoc}(f_3); \text{assume } \forall z \neq x. f_3(z) = \text{old_f}_3(z)$$

Example

```
class Pair { Object first; Object second; }  
void printPair(p : Pair) { ... }  
void printBoth(x : Object, y : Object)  
modifies first, second // ?  
{  
    Pair p = new Pair();  
    p.first = x;  
    p.second = y;  
    printPair(p);  
}
```

printBoth(x1,y1)

Allowing Modification of Fresh Objects

Suppose there are fields and variables f_1, f_2, f_3 (denoted f)

procedure $\text{foo}(x)$:

requires $P(x, f)$

modifies $x.f_3$

ensures $Q(x, f, f')$

$\text{foo}(E) \rightarrow$

assert($P(E, f)$);

old_f = f; $\text{old_alloc} = \text{alloc};$

havoc $f_3, f_2, f_1, \text{alloc}$

assume $\forall z \in \text{old_alloc} . f_1(z) = \text{old_}f_1(z) \wedge f_2(z) = \text{old_}f_2(z)$

assume $Q(E, \text{old_}f, f)$ $(z \neq x \rightarrow f_3(z) = \text{old_}f_3(z))$

assume ($\text{old_alloc} \subseteq \text{alloc}$)

Data remains same if: 1) existed and 2) not listed in m.clause

Quiz will be this Tuesday!
(not open book)

Bring: paper, pen, EPFL Camipro card

Now we can model many programs

We can represent any body of sequential code inside one procedure.

Our loop invariants, pre/post conditions can become very complex

Linked List Implementation

```
class List {  
    private List next;  
    private Object data;  
    private static List root;  
    content = "objects reachable from 'root' = {root} • next* • data  
    content = add(content) ∪ {x}  
  
    public static void addNew(Object x) {  
        List n1 = new List();  
        n1.next = root;  
        n1.data = x;  
        root = n1;  
    }  
}
```

Doubly Linked

```

assume P;
if (first == null) {
    first = n;
    n.next = null;
    n.prev = null;
} else {
    n.next = first;
    first.prev = n;
    n.prev = null;
    first = n;
}

```

$$\begin{aligned}
 &n \neq \text{null} \wedge \\
 &\text{next}(n) = \text{null} \wedge \text{prev}(n) = \text{null} \wedge \\
 &\text{prev}(\text{first}) = \text{null} \wedge Q
 \end{aligned}$$

$\text{prev}(\text{null}) = \text{null}$
 $\text{next}(\text{null}) = \text{null}$

$\square \text{ assume } (\text{first} \neq \text{null})$
 $\text{assert } (n \neq \text{null});$
 $\text{next} = \text{next}(n := \text{first})$
 $\text{prev} = \text{prev}(\text{first} := n)$
 $\text{prev} = \text{prev}(n := \text{null})$
 $\text{first} = n$

assert Q;

$$\begin{aligned}
 &\forall x. \forall y. \text{prev}(x) = y \rightarrow \\
 &\quad (y \neq \text{null} \rightarrow \text{next}(y) = x) \wedge \\
 &\quad (y = \text{null} \wedge x \neq \text{null} \rightarrow (\forall z. \text{next}(z) \neq x))
 \end{aligned}$$

```

assume P;
if (first == null) {
    first = n;
    n.next = null;
    n.prev = null;
} else {
    n.next = first;
    first.prev = n;
    n.prev = null;
    first = n;
}

```

$$\left[\begin{array}{l} n \neq \text{null} \wedge \\ \text{next}(n) = \text{null} \wedge \text{prev}(n) = \text{null} \wedge \\ \text{prev}(\text{first}) = \text{null} \wedge Q \end{array} \right.$$

```

assert Q;

```

$$\left[\begin{array}{l} \forall x. \forall y. \text{prev}(x) = y \rightarrow \\ (y \neq \text{null} \rightarrow \text{next}(y) = x) \wedge \\ (y = \text{null} \wedge x \neq \text{null} \rightarrow (\forall z. \text{next}(z) \neq x)) \end{array} \right.$$

Reachability

```
assume P;  
if (first == null) {  
    first = n;  
    n.next = null;  
    n.prev = null;  
} else {  
    n.next = first;  
    first.prev = n;  
    n.prev = null;  
    first = n;  
}
```

```
assert Q;
```

$$\left[\begin{array}{l} n \neq \text{null} \wedge \\ \text{next}(n) = \text{null} \wedge \text{prev}(n) = \text{null} \wedge \\ \text{prev}(\text{first}) = \text{null} \wedge Q \end{array} \right.$$
$$\left[\begin{array}{l} \forall x. \forall y. \text{prev}(x) = y \rightarrow \\ (y \neq \text{null} \rightarrow \text{next}(y) = x) \wedge \\ (y = \text{null} \wedge x \neq \text{null} \rightarrow (\forall z. \text{next}(z) \neq x)) \end{array} \right.$$

How to prove such verification
conditions automatically?
