Automating First-Order Logic Proofs Using Resolution

Viktor Kunčak, EPFL

Automating first-order logic (FOL)

First-order logic supports arbitrary (uninterpreted) predicates and functions

their meaning will be constrained through axioms

FOL can be used in practice to formalize most of mathematics (e.g. through set theory axioms), and thus all of program verification problems. To prove whether a property holds, we can proceed as follows:

- describe the property using a formula F
- describe the functions and relations in F using a sequence of axioms S

Check if the sequence $(\neg F; S)$ is contradictory. If yes, then F follows from S

Completeness: there is a procedure that will, if F does follow from S, in finite time establish this (we do not know how long it will take, if it does not hold, it loops). We give one such procedure: resolution for FOL.

Running example of FOL formula

Here is a first-order logic formula:

$$(\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. (R(x,y) \rightarrow \forall z. R(x,f(y,z)))) \land (\forall x. (P(x) \lor P(f(x,a)))) \rightarrow \forall x.\exists y. (R(x,y) \land P(y))$$

Note that it contains:

- ▶ propositional operations $\land, \lor, \neg, \rightarrow$
- variables x, y
- ► quantifiers ∀,∃ (only over the variables)
- function symbols and constants: f, a
- predicate symbols: P, R

First-order logic syntax and terminology

A first-order signature \mathcal{L} (akka language) specifies a countable set of function symbols f (constants c are functions symbols taking no arguments), and predicate symbols p. Syntax of formulas (F) and terms (t) in first-order logic:

 $F ::= p(t_1, \dots, t_n) \mid \forall x.F \mid \exists x.F \mid \top \mid \bot \mid \neg F \mid F_1 \land F_2 \mid F_1 \lor F_2 \mid F_1 \rightarrow F_2 \mid F_1 \leftrightarrow F_2$ $t ::= x \mid c \mid f(t_1, \dots, t_n)$

where $x \in Var$ denotes variables, which form a countably infinite fixed set. ar denotes arity of functions and predicate symbols; e.g. ar(f) = 2 means f takes two arguments, so it is allowed to form a term $f(t_1, t_2)$, and also ar(p) = 2 for predicate symbol p means that it is allowed to form formula $p(t_1, t_2)$. We interpret each f as $\overline{f} : D^{ar(f)} \to D$ and each p as $\overline{p} : D^{ar(p)} \to \{0,1\}$ (or: $\subseteq D^{ar(p)}$)

We call $p(t_1,...,t_n)$ an *atomic formula* (contains no logical connectives or quantifiers). A *literal* is such an atomic formula, or its negation $\neg p(t_1,...,t_n)$ A *clause* is a disjunction of literals, e.g. $\neg p(x, f(y)) \lor q(y) \lor \neg r(x, z)$

Example of a FOL signature

We will look at the signature $\mathcal{L} = \{P, R, a, f\}$ where

- P is a predicate symbol, ar(P) = 1
- R is a predicate symbol, ar(R) = 2
- a is a constant
- f is a function symbol, ar(f) = 2

An interpretation for this language is then any structure (D, e) where

- $D \neq \emptyset$ (it can be finite or infinite)
- $\blacktriangleright e(P): D \to \{0,1\}$
- ► $e(R): D^2 \rightarrow \{0,1\}$

•
$$e(a) \in D$$

►
$$e(f): D^2 \rightarrow D$$

Example: $D = \{0, 1, 2, ...\}$ (non-negative integers) and:

•
$$e(P)(n) = \text{ if } (2|n) \text{ then } 1 \text{ else } 0$$

•
$$e(R)(x,y) = \text{ if } (x \le y) \text{ then } 1 \text{ else } 0$$

$$\blacktriangleright e(a) = 1$$

•
$$e(f)(x,y) = x + y$$

Semantics given an interpretation

Taking that interpretation, $D = \{0, 1, 2, ...\},\$

e(P)(n) = if (2|n) then 1 else 0
 e(R) = if (x ≤ y) then 1 else 0
 e(a) = 1
 e(f)(x,y) = x + y

we can talk about the truth value of any closed formula, e.g.:

(text, or tree)
$$\begin{array}{l} (\forall x.\exists y. \ R(x,y)) \land \\ (\forall x.\forall y. \ (R(x,y) \rightarrow \forall z. \ R(x,f(y,z)))) \land \\ (\forall x. \ (P(x) \lor P(f(x,a)))) \\ \rightarrow \forall x.\exists y. \ (R(x,y) \land P(y)) \end{array}$$

Its truth is precisely the truth of this (symbols are replaced with their value in e):

$$(\text{true or false}) \qquad \begin{array}{l} (\forall x.\exists y. \ x \leq y) \land \\ (\forall x.\forall y. \ x \leq y \ \rightarrow \forall z. \ x \leq (y+z)) \land \\ (\forall x. \ (2|x) \lor (2|x+1)) \\ \rightarrow \forall x.\exists y. \ (x \leq y \land (2|y)) \end{array}$$

Semantics in general: interpreter written in set theory

A first-order *interpretation* is I = (D, e) where $D \neq \emptyset$ and *e* maps constants, function and predicate symbols as follows:

- ▶ each predicate symbol p with ar(p) = n into $e(p) : D^n \rightarrow \{0, 1\}$
- ▶ each function symbol f with ar(f) = n into a total function of n arguments, $e(f): D^n \to D$ (and each constant c into element of D, i.e., $e(c) \in D$)
- ▶ maps each variable x to element of D, i.e., $e(x) \in D$

We then define $\llbracket F \rrbracket_I \in \{0, 1\}$ to denote whether F is true (1) or false (0) false in interpretation I. The rules are the expected rules recursive on the formula tree:

$$\begin{split} \llbracket F_1 \wedge F_2 \rrbracket_I &= \llbracket F_1 \rrbracket_I \wedge \llbracket F_2 \rrbracket_I & \llbracket F_1 \vee F_2 \rrbracket_I & \llbracket F_1 \rrbracket_I \vee \llbracket F_2 \rrbracket_I & \llbracket \neg F \rrbracket_I & \neg \llbracket F \rrbracket_I & \llbracket \bot \rrbracket_I = 0 \\ & \llbracket f(t_1, \dots, t_n) \rrbracket_I &= e(f)(\llbracket t_1 \rrbracket_I, \dots, \llbracket t_n \rrbracket_I) & \llbracket p(t_1, \dots, t_n) \rrbracket_I &= e(p)(\llbracket t_1 \rrbracket_I, \dots, \llbracket t_n \rrbracket_I) \\ & \llbracket \forall x.F \rrbracket_{(D,e)} &= \text{ if } (\forall d \in D. (\llbracket F \rrbracket_{(D,e[x:=d])} = 1)) \text{ then } 1 \text{ else } 0 \\ & \llbracket \exists x.F \rrbracket_{(D,e)} &= \text{ if } (\exists d \in D. (\llbracket F \rrbracket_{(D,e[x:=d])} = 1)) \text{ then } 1 \text{ else } 0 \\ & \text{ where } e[x:=d](y) &= (\text{ if } x = y \text{ then } d \text{ else } e(y)) \end{split}$$

What makes this logic first order

$$\begin{split} & [\![\forall x.F]\!]_{(D,e)} = \mathrm{if}\big(\{d \in D \mid [\![F]\!]_{(D,e[x:=d])} = 1\} = D\big) \text{ then } 1 \text{ else } 0 \\ & [\![\exists x.F]\!]_{(D,e)} = \mathrm{if}\big(\{d \in D \mid [\![F]\!]_{(D,e[x:=d])} = 1\} \neq \emptyset\big) \text{ then } 1 \text{ else } 0 \end{split}$$

We can quantify over variables $\forall x.F$, $\exists x.F$, which are interpreted over D, and we can nest quantifiers, e.g. $\forall x.\exists y. (p(x,y) \land q(y,x))$.

We *cannot* write a FOL formula that quantifies over function and relation symbols (that would be *second* or, generally, *higher* order).

The meaning of function and relation symbols is fixed in *e* of interpretation I = (D, e).

To make statements that do not depend on a particular interpretation, we use concepts of *satisfiability* and *validity*:

F is valid if, for all interpretations (D, e)
 (for arbitrarily small or large sets D and all possible choices of e), [[F]]_(D,e) = 1

▶ *F* is satisfiable if there exists an interpretation (D, e) such that $\llbracket F \rrbracket_{(D,e)} = 1$

Satisfiability and validity: illustration

Take first-order logic (FOL) formula

 $\forall x.\exists y. (p(x,y) \land q(y,x))$

Its **satisfiability** is, by definition, equivalent to a statement:

$$\exists \mathbf{D} \neq \emptyset. \ \exists \overline{\mathbf{p}}, \overline{\mathbf{q}} \subseteq \mathbf{D}^2. \ \forall x \in D. \exists y \in D. \ ((\overline{p}(x, y) \land \overline{q}(y, x)) = 1)$$

Its validity is, by definition, equivalent a statement:

$$\forall \mathbf{D} \neq \emptyset. \ \forall \overline{\mathbf{p}}, \overline{\mathbf{q}} \subseteq \mathbf{D}^2. \ \forall x \in D. \exists y \in D. \ ((\overline{p}(x, y) \land \overline{q}(y, x)) = 1)$$

The domain, functions, and relations are either all existentially quantified (if we ask about satisfiability) or all universally quantified (if we ask about validity).

Observation: F is valid if and only if $\neg F$ is not satisfiable. We will be checking satisfiability (aiming for a negative answer).

Back to our example

Consider our example formula *F*:

$$(\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. R(x,y) \rightarrow \forall z. R(x,f(y,z))) \land (\forall x. P(x) \lor P(f(x,a))) \rightarrow \forall x.\exists y. R(x,y) \land P(y)$$

We have seen it has an interpretation where it is true, so F is satisfiable. We are interested in checking its *validity*.

To do that, we will check the satisfiability of $\neg F$.

$$\neg ((\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. R(x,y) \rightarrow \forall z. R(x,f(y,z))) \land (\forall x. P(x) \lor P(f(x,a))) \land \forall x.\exists y. R(x,y) \land P(y))$$

In general, we will transform $\neg F$ into a *normal form*.

Negation normal form for FOL

Observation: If $F \leftrightarrow G$ is a valid FOL formula, then inside any other FOL formula H we can replace a sub-formula F with G without changing the truth value of the formula: $H[F] \rightsquigarrow H[G]$.

We can transform formulas to negation normal using transformations such as these:

In negation normal form, negation applies only to atomic formulas and the only other propositional connectives are \land , \lor .

Compute negation normal form

$$\neg \left(\left((\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. (R(x,y) \rightarrow \forall z. R(x,f(y,z)))) \land (\forall x. P(x) \lor P(f(x,a))) \right) \rightarrow \forall x.\exists y. R(x,y) \land P(y) \right)$$

becomes:

Compute negation normal form

$$\neg \left(\left((\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. (R(x,y) \rightarrow \forall z. R(x,f(y,z)))) \land (\forall x. P(x) \lor P(f(x,a))) \right) \rightarrow \forall x.\exists y. R(x,y) \land P(y) \right)$$

becomes:

$$(\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. (\neg R(x,y) \lor \forall z. R(x,f(y,z)))) \land (\forall x. (P(x) \lor P(f(x,a)))) \land (\exists x.\forall y. (\neg R(x,y) \lor \neg P(y)))$$

Compute negation normal form

$$\neg \Big(\big((\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. (R(x,y) \to \forall z. R(x,f(y,z)))) \land (\forall x. P(x) \lor P(f(x,a))) \Big) \to \forall x.\exists y. R(x,y) \land P(y) \Big)$$

becomes:

$$(\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. (\neg R(x,y) \lor \forall z. R(x,f(y,z)))) \land (\forall x. (P(x) \lor P(f(x,a)))) \land (\exists x.\forall y. (\neg R(x,y) \lor \neg P(y)))$$

Coming next: get rid of existential quantifiers!

Introducing a Skolem function

Observe that e.g. the following formula is valid: $p(x, f(x)) \rightarrow \exists y.p(x, y)$. Indeed, fix any interpretation (D, e) and assume p(x, f(x)). To prove $\exists y.p(x, y)$, just let y be f(x). Consequently, also

$$(\forall x.p(x,f(x))) \rightarrow (\forall x.\exists y.p(x,y))$$

is valid. A form of converse is also true. Take any interpretation (D, e) in which $\forall x.\exists y.p(x,y)$ holds. Then there exists $y_d \in D$ such that $e(p)(x_d, y_d) = 1$. Construct (by axiom of choice) a function \overline{f} that assigns to every element $x_d \in D$ one $y_d \in D$ for which $e(p)(x_d, y_d) = 1$. Extend the signature with a **new function symbol** f (Skolem function, according to (W) Thoralf Skolem) that does not appear in the formula. Define a new interpretation l' = (D, e') (with the same domain) as $e' = e[f := \overline{f}]$, that is, e' behaves like e but maps a new symbol f to the function \overline{f} . Then $[\forall x.p(x, f(x))]_{l'} = 1$. We can do this not just for p but any quantifier-free formula and preserve satisfiability in a larger formula.

Skolemization in general

In a formula that is in negation normal form, replace a subformula

 $\exists y. F(x_1,\ldots,x_n,y)$

with

$$F(x_1,\ldots,x_n,g(x_1,\ldots,x_n))$$

where g is a new function symbol (Skolem function) of arity n and $\{x_1, \ldots, x_n\}$ are the variables free in F, computed like this:

$$FV(c) = \emptyset, FV(x) = \{x\}$$

$$FV(f(t_1,...,t_n)) = FV(t_1) \cup ... \cup FV(t_n) = FV(p(t_1,...,t_n))$$

$$FV(F_1 \wedge F_2) = FV(F_1) \cup FV(F_2) FV(\neg F) = FV(F)$$

$$FV(\forall x.F) = FV(F) \setminus \{x\} = FV(\exists x.F)$$

If we have quantifiers $Q_1 x_1 \dots Q_n x_n F$ we start eliminating from outside (left) and then Skolem function arguments for $\exists x_i$ are only \forall quantified variables among x_1, \dots, x_{i-1} . Skolemized form for the example

$$\begin{array}{ll} (\forall x. \exists y. \ R(x,y)) \land & y \rightsquigarrow s_1(x) \\ (\forall x. \forall y. \ (\neg R(x,y) \lor \forall z. \ R(x,f(y,z)))) \land \\ (\forall x. \ (P(x) \lor P(f(x,a)))) \land \\ (\exists x. \forall y. \ (\neg R(x,y) \lor \neg P(y))) & x \rightsquigarrow s_2 \end{array}$$

becomes:

 $(\forall x. R(x, s_1(x))) \land$ $(\forall x. \forall y. (\neg R(x, y) \lor \forall z. R(x, f(y, z)))) \land$ $(\forall x. (P(x) \lor P(f(x, a)))) \land$ $(\forall y. (\neg R(s_2, y) \lor \neg P(y)))$

Moving quantifiers and conjunctive normal form

Note that all bound quantified variables can be renamed while preserving equivalence and that quantifier can be pulled in or out of formula where it does not occur:

•
$$(\forall x.F) \leftrightarrow \forall y.F[x := y]$$
, where y is fresh

$$\blacktriangleright (\forall x.F) \lor G \longleftrightarrow \forall x.(F \lor G)$$

$$\blacktriangleright (\forall x.F) \land G \longleftrightarrow \forall x.(F \land G)$$

We can thus put formulas outwards. If we choose, we can obtain: *prenex normal form*, a formula of the form

$$Q_1 x_1. Q_2 x_2. \ldots Q_n x_n. G$$

where $Q_i \in \{\forall, \exists\}$ and G has no quantifiers.

We can then transform G to conjunctive normal form, as for propositional logic:

 $\blacktriangleright (F \land G) \lor H \leftrightarrow (F \lor H) \land (G \lor H)$

We can also introduce fresh predicate symbols to avoid exponential blowup.

Conjunction of clauses

Theorem: each formula F can be transformed into an equisatisfiable formula of the form:

$$(\forall x_1,\ldots,x_n.C_1)\wedge\ldots\wedge(\forall x_1,\ldots,x_n.C_m)$$

where each C_i is quantifier free and, moreover, a disjunction of first-order literals. Note: a first-order literal is either an atomic formula, that is $p(t_1,...,t_k)$ where p is a predicate symbol, or a negation of an atomic formula, $\neg p(t_1,...,t_k)$.

Indeed, we have seen how to move \neg to predicates (NNF), eliminate \exists , and pull \forall and \land to the outside, leaving \lor applied to literals.

Each C_i is a (first-order) clause. We can also view it as a set, because the order of disjuncts does not matter up to equivalence. Clause that is an empty set means \bot . For a given formula F, denote the set of obtained clauses $\{C_1, \ldots, C_m\}$ by clauses(F). We omit universal quantifiers because all variables are universally quantified. We use a convention to denote variables by x, y, z, \ldots and constants by a, b, c, \ldots

Sets of formulas when checking satisfiability

We define that a set of formulas S is true in an interpretation I if *every* formula is true in that interpretation:

$$\llbracket S \rrbracket_I = \text{ if } (\forall F \in S. \llbracket F \rrbracket_I = 1) \text{ then } 1 \text{ else } 0$$

If S is finite then $[S]_I = [\bigwedge_{F \in S} S]_I$.

We say two sets are *equivalent* iff the set of interpretations in which they are true are equal.

We say that S is satisfiable iff there exists I such that $[S]_I = 1$.

Thus, F is satisfiable iff clauses(F) is satisfiable.

Clauses for the example

$$(\forall x. R(x, s_1(x))) \land (\forall x. \forall y. (\neg R(x, y) \lor \forall z. R(x, f(y, z)))) \land (\forall x. (P(x) \lor P(f(x, a)))) \land (\forall y. (\neg R(s_2, y) \lor \neg P(y)))$$

gives the set of clauses:

$$\{R(x, s_1(x)), \\ \neg R(x, y) \lor R(x, f(y, z)), \\ P(x) \lor P(f(x, a)), \\ \neg R(s_2, y) \lor \neg P(y) \}$$

Clauses for the example

$$(\forall x. R(x, s_1(x))) \land (\forall x. \forall y. (\neg R(x, y) \lor \forall z. R(x, f(y, z)))) \land (\forall x. (P(x) \lor P(f(x, a)))) \land (\forall y. (\neg R(s_2, y) \lor \neg P(y)))$$

gives the set of clauses:

$$\{ R(x, s_1(x)), \\ \neg R(x, y) \lor R(x, f(y, z)), \\ P(x) \lor P(f(x, a)), \\ \neg R(s_2, y) \lor \neg P(y) \}$$

or, if we represent clauses themselves as sets:

$$\{ \{ R(x, s_1(x)) \}, \\ \{ \neg R(x, y), R(x, f(y, z)) \}, \\ \{ P(x), P(f(x, a)) \}, \\ \{ \neg R(s_2, y), \neg P(y) \} \}$$

Applying sound inference rules

We say that an inference rule

$$\frac{F_1 \dots F_n}{G} \tag{(*)}$$

is **sound** iff the formula $(F_1 \land ... \land F_n) \rightarrow G$ is valid. **Observation.** Let (*) be a sound inference rule and $F_1, ..., F_n \in S$. Then S and $S \cup \{G\}$ are equivalent.

Example: using convention that variables are \forall quantified, the **instantiation** rule

$$\frac{C}{C[\overline{x}:=\overline{t}]}$$

is sound, where $C[\overline{x} := \overline{t}]$ denotes substituting variables of C by some terms. In general, \overline{t} may contain other variables. Special cases of instantiation are:

- renaming: replace variables with fresh variables
- ground instantiation: replace variables with ground terms, that have no variables (built only from constants and function symbols)

Resolution and for FOL clauses

The following formula (transitivity of universal implication) is easily proven to be valid for all formulas F, G, H, where \overline{x} denotes the finite list of all free variables in F, G, H:

$$\left(\left(\forall \overline{x}. \ (F \to G) \right) \land \ \left(\forall \overline{x}. \ (G \to H) \right) \right) \quad \to \quad \left(\forall \overline{x}. (F \to H) \right)$$

Write it down as an inference rule, assume that all formulas universally quantified:

$$\frac{F \to G \qquad G \to H}{F \to H}$$

Expressing \rightarrow using \lor and \neg :

$$\frac{\neg F \lor G \qquad \neg G \lor H}{\neg F \lor H}$$

Let G be a literal L, let $\neg F$ be equivalent to clause C_1 and H to clause C_2 . We get:

$$\frac{C_1 \vee L \qquad \neg L \vee C_2}{C_1 \vee C_2}$$
 resolution (simple, without unification)

Resolution with instantiation

We call literals *L* and $\neg L$ complementary.

If literals are not complementary, we may still be able to apply substitution rule to make them complementary:

$$\frac{C_1' \lor L'}{C_1 \lor L} \qquad \frac{\neg L'' \lor C_2''}{\neg L \lor C_2}$$
$$C_1 \lor C_2$$

To check whether we can find a substitution to make L' and L'' identical (\equiv), we can use (syntactic, first-order) **unification**, which has a linear-time algorithm.

(W) Unification (computer science)

We rename variables in two clauses so that they are disjoint, the instantiate them by computing *most general unifier* computation so that literals become complementary (one is an atomic formula and the other its negation).

- $1 R(x, s_1(x))$ $2 \neg R(x, y) \lor R(x, f(y, z))$ $3 P(x) \lor P(f(x, a))$
- $4 \neg R(s_2, y) \lor \neg P(y)$

- $1 R(x, s_1(x))$
- $2 \neg R(x,y) \lor R(x,f(y,z))$
- 3 $P(x) \lor P(f(x,a))$
- $4 \neg R(s_2, y) \lor \neg P(y)$
- 5 (1,2): $R(x, f(s_1(x), z)) \quad y \rightsquigarrow s_1(x)$

- $1 \ R(x, s_1(x))$
- $2 \neg R(x,y) \lor R(x,f(y,z))$
- 3 $P(x) \lor P(f(x,a))$
- $4 \neg R(s_2, y) \lor \neg P(y)$
- 5 (1,2): $R(x, f(s_1(x), z)) \quad y \rightsquigarrow s_1(x)$
- 6 (1,4): $\neg P(s_1(s_2)) \xrightarrow{x \leftrightarrow s_2, y \leftrightarrow s_1(x)}$

- $1 \ R(x, s_1(x))$
- $2 \neg R(x,y) \lor R(x,f(y,z))$
- 3 $P(x) \lor P(f(x,a))$
- $4 \neg R(s_2, y) \lor \neg P(y)$
- 5 (1,2): $R(x, f(s_1(x), z)) \quad y \rightsquigarrow s_1(x)$
- 6 (1,4): $\neg P(s_1(s_2)) \quad x \rightsquigarrow s_2, y \rightsquigarrow s_1(x)$
- 7 (3,6): $P(f(s_1(s_2), a)) \xrightarrow{x \leftrightarrow s_1(s_2)}$

- $1 \ R(x, s_1(x))$
- $2 \neg R(x,y) \lor R(x,f(y,z))$
- 3 $P(x) \lor P(f(x,a))$
- $4 \neg R(s_2, y) \lor \neg P(y)$
- 5 (1,2): $R(x, f(s_1(x), z)) \quad y \rightsquigarrow s_1(x)$
- 6 (1,4): $\neg P(s_1(s_2)) \quad x \rightsquigarrow s_2, y \rightsquigarrow s_1(x)$
- 7 (3,6): $P(f(s_1(s_2), a)) \xrightarrow{x \rightsquigarrow s_1(s_2)}$
- 8 (4,7): $\neg R(s_2, f(s_1(s_2), a)) \quad y \rightsquigarrow f(s_1(s_2), a)$

- $1 R(x, s_1(x))$
- $2 \neg R(x,y) \lor R(x,f(y,z))$
- 3 $P(x) \lor P(f(x,a))$
- $4 \neg R(s_2, y) \lor \neg P(y)$
- 5 (1,2): $R(x, f(s_1(x), z)) \quad y \rightsquigarrow s_1(x)$
- 6 (1,4): $\neg P(s_1(s_2)) \quad x \rightsquigarrow s_2, y \rightsquigarrow s_1(x)$
- 7 (3,6): $P(f(s_1(s_2), a)) \xrightarrow{x \rightsquigarrow s_1(s_2)}$
- 8 (4,7): $\neg R(s_2, f(s_1(s_2), a)) \quad y \rightsquigarrow f(s_1(s_2), a)$
- 9 (5,8): $\perp x \rightsquigarrow s_2$

Apply resolution and instantiation to clauses in our example:

$$1 R(x, s_1(x))$$

$$2 \neg R(x,y) \lor R(x,f(y,z))$$

3 $P(x) \lor P(f(x,a))$

$$4 \neg R(s_2, y) \lor \neg P(y)$$

5 (1,2):
$$R(x, f(s_1(x), z)) \quad y \rightsquigarrow s_1(x)$$

6 (1,4):
$$\neg P(s_1(s_2)) \xrightarrow{x \leftrightarrow s_2, y \leftrightarrow s_1(x)}$$

7 (3,6):
$$P(f(s_1(s_2), a)) \xrightarrow{x \to s_1(s_2)}$$

- 8 (4,7): $\neg R(s_2, f(s_1(s_2), a)) \quad y \rightsquigarrow f(s_1(s_2), a)$
- 9 (5,8): $\perp x \rightsquigarrow s_2$

We can derive \bot from the set of clauses.

Thus, the set of clauses is unsatisfiable. The formula we started from as well.

Conclusion of the procedure on this example

Thus, the formula before negation:

$$(\forall x.\exists y. R(x,y)) \land (\forall x.\forall y. R(x,y) \rightarrow \forall z. R(x,f(y,z))) \land (\forall x. P(x) \lor P(f(x,a))) \rightarrow \forall x.\exists y. R(x,y) \land P(y)$$

was **valid**. We have proven that this formula holds in all possible models (no matter how small, large, or complex they might be).

Remarkably, resolution with instantiation is refutationally complete: if the formula is valid, then from the clauses equisatisfiable to its negation we will find a contradiction.
