Abstract Interpretation on Control-Flow Graphs

Example

`k=1; while(k < 100) { k=k+3 }; assert(k <= 255)`

`k=1; loop {assume(k < 100); k=k+3};`

`assume(k>=100); assert(k <= 255)`

$$r = \{(k, k') \mid (k < 100 \wedge k' = k + 3)\}$$

Approximating $\text{sp}(\{1\}, r^*)$

$\text{post}(P) = \{1\} \cup \text{sp}(P, r) = \{1\} \cup \{k+3 \mid k \in P, k < 100\}$

$\text{post}^n(\{\})$:

$\{\}, \{1\}, \{1, 4\}, \dots, \{1, \dots, 97\}, \{1, \dots, 97, 100\},$
 $\{1, \dots, 97, 100\}$

Multiple variables

Wish to track an interval for each variable

We track not $[L,U]$ but $([L1,U1],[L2,U2])$

If program state is (x,y) , define

$$\gamma_2([L1,U1],[L2,U2]) = \{(x,y) \mid L1 \leq x \leq U1, L2 \leq y \leq U2\}$$
$$= \mathcal{I}_1[L1,U1] \times \mathcal{I}_1[L2,U2]$$

$$\alpha(p) = ([L1,U1],[L2,U2])$$

$$L1 =$$

$$U1 =$$

$$L2 =$$

$$U2 =$$

Product of Partial Orders

(A_i, \leq_i) partial orders for $i \in J$

(A, \leq) given by $A = \{f : J \rightarrow \bigcup_{i \in J} A_i, \forall i. f(i) \in A_i\}$

$f, g \in A$ ordered by

$$f \leq g \Leftrightarrow \forall i. f(i) \leq_i g(i)$$

example: $J = \{1, 2\}$

Then (A, \leq) is a partial order. Moreover:

If (A_i, \leq_i) all have lub, then so does (A, \leq) .

If (A_i, \leq_i) all have glb, then so does (A, \leq) .

Example: Counter and a Mode

```
mode = 1
x = 0
while (-100 < x && x < 100) {
  if (mode == 1) {
    x = x + 10
    mode = 2
  } else {
    x = x - 1
    mode = 1
  }
}
assert(1 <= mode && mode <= 2 && x <= 109)
```

Two Counters

```
x = 0
y = 0
while (x < 100) {
  x = x + 1
  y = y + 2
}
assert(y <= 200)
```

Non-relational analysis: tracks each variable separately.
It often loses correlations between them.

Beyond One Loop

- Precise formulation of one-step relation for a CFG
- The form of post in new form: deriving collecting semantics
- Example collecting semantics for a program
- Abstraction of this semantics in example
- Abstract Interpretation Recipe
- Termination of fixpoint computation
- Choatic iteration
- Widening
